Package 'FRAPO'

June 19, 2013

Version 0.3-8

Date 2013-06-15

Title Financial Risk Modelling and Portfolio Optimisation with R

Depends R (>= 2.11), methods, quadprog, Rglpk, timeSeries

Suggests xts, zoo, Rsolnp

Description Accompanying package of the book 'Financial Risk Modelling and Portfolio Optimisation with R'. The data sets used in the book are contained in this package.

LazyData TRUE

License GPL (>= 2)

BookEx

Utility functions for handling book examples

Description

Utility functions for returning a list of the included examples and displaying, executing, saving and editing the example codes are provided.

Usage

```
listEx()
showEx(Example)
saveEx(Example)
editEx(Example, ...)
runEx(Example, ...)
```

Arguments

Example Characater, the name of the example as contained in listEx().
... Ellipsis argument. See details.

Details

The ellipsis arguments in the function editEx() are passed down to the function file.edit(). If the option editor is unset and/or a different editor shall be employed for openening the example code, then the ellipsis argument can be utilised by editor = "foo", wherey foo is the name of the editor to be used.

The ellipsis arguments in the function runEx() are passed down to the function source().

Value

listEx

Returns a character vector of the examples' names.

showEx

Returns the example of of Example to the console.

saveEx

Returns a logical whether the saving of the R code example into the working directory was successful.

editEx

Opens a copy of the example code in an editor.

runEx

Executes the example code.

4 capser

Author(s)

Bernhard Pfaff

See Also

```
file.edit, source
```

Examples

```
## Not run:
listEx()
showEx(Example = "Part1Chapter3Ex2")
saveEx(Example = "Part1Chapter3Ex2")
runEx(Example = "Part1Chapter3Ex2", echo = TRUE)
editEx(Example = listEx()[1], editor = "emacs")
## End(Not run)
```

capser

Capping a series to bounds

Description

The values of a series that are absolute greater than min and/or max are capped to these specified values.

Usage

```
capser(y, min, max)
```

Arguments

У	Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.
min	Numeric, minimum value for the series.
max	Numeric, maximim value for the series.

Value

An object of the same class as y, containing the truncated series.

DivMeasures 5

Methods

y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.

- y = ''matrix'' The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the es trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- y = "zoo" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.

Examples

```
data(StockIndex)
y <- StockIndex[, "SP500"]
cs <- capser(y, min = 100, max = 200)
head(cs)</pre>
```

DivMeasures

Diversification Measures

Description

These functions compute the diversification ratio, the volatility weighted average correlation and concentration ratio of a portfolio.

Usage

```
dr(weights, Sigma)
cr(weights, Sigma)
rhow(weights, Sigma)
```

Arguments

weights Vector: portfolio weights.

Sigma Matrix: Variance-covariance matrix of portfolio assets.

Details

The diversification ratio of a portfolio is defined as:

$$DR(\omega) = \frac{\sum_{i=1}^{N} \omega_i \sigma_i}{\sqrt{\omega' \Sigma \omega}}$$

for a portfolio of N assets and ω_i signify the weight of the i-th asset and σ_i its standard deviation and Σ the variance-covariance matrix of asset returns. The diversification ratio is therefore the weighted average of the assets' volatilities divided by the portfolio volatility.

The concentration ration is defined as:

$$CR = \frac{\sum_{i=1}^{N} (\omega_i \sigma_i)^2}{(\sum_{i=1}^{N} \omega_i \sigma_i)^2}$$

and the volatility-weighted average correlation of the assets as:

$$\rho(\omega) = \frac{\sum_{i>j}^{N} (\omega_i \sigma_i \omega_j \sigma_j) \rho_{ij}}{\sum_{i>j}^{N} (\omega_i \sigma_i \omega_j \sigma_j)}$$

The following equation between these measures does exist:

$$DR(\omega) = \frac{1}{\sqrt{\rho(\omega)(1 - CR(\omega)) + CR(\omega)}}$$

Value

numeric, the value of the diversification measure.

ESCBFX

ESCB FX Reference Rates

Description

Daily spot rates of major currencies against the EUR.

Usage

```
data(ESCBFX)
```

Format

A data frame with 3,427 daily observations of the spot currency rates rates AUD, CAD, CHF, GBP, HKD, JPY and USD against EUR. The sample starts in 1999-01-04 and ends in 2012-04-04.

Details

The data has been retrieved from the Statistical Data Warehouse (SDW) Internet-Site of the ECB. In case of missing data entries due to holidays, the last observed data point has been carried forward.

INDTRACK1

INDTRACK1: Hang Seng Index and Constituents

Description

Weekly price data of the Hang Seng index and 31 constituents.

Usage

```
data(INDTRACK1)
```

Format

A data frame with 291 weekly observations of the index and 31 members of the Hang Seng index. The sample starts in March 1991 and ends in September 1997.

Details

The data set was used in the first two references below. Stocks with missing values during the sample period have been discarded. The data was downloaded from DATASTREAM and has been anonymized. The first columne refers to the index data itself. See the attached license file that is part of this package: 'BeasleyLicence'.

mrc 17

mrc

Marginal Contribution to Risk

Description

This function returns the marginal contributions to portfolio risk, whereby the latter is defined in terms of the portfolio standard deviation.

Usage

```
mrc(weights, Sigma, percentage = TRUE)
```

Arguments

weights Vector: portfolio weights.

Sigma Matrix: Variance-covariance matrix of portfolio assets.

percentage Logical, whether the marginal risk contributions shall be returned as percent-

ages that sum to 100 (default) or as decimal numbers.

Details

The marginal contributions to risk are computed for a given dispersion matrix and weight vector.

Value

numeric, the marginal risk contributions of the portfolio's asset.

Multi Asset Index Data

Author(s)

Bernhard Pfaff

Mu1	tiAsset	

Description

Month-end price data of stock and bond indices and gold.

Usage

```
data(MultiAsset)
```

Format

A data frame with 85 month-end observations of stock and bond indices and gold, represented by the ETF SPDR Gold. The sample starts at 2004-11-30 and ends in 2011-11-30.

NASDAQ

Details

The data set has been obtained from Yahoo Finance and hereby the unadjusted closing prices have been retrieved. If a month-end value was not reported, the value of the previous day has been used. The Yahoo mnemonics with the respective item description are listed below:

GSPC United States: S & P 500 Index (Equity)

RUA United States: Russell 3000 Index (Equity)

GDAXI Germany: DAX (XETRA) Index (Equity)

FTSE United Kingdom: FTSE 100 Index (Equity)

N225 Japan: Nikkei 225 Index (Equity)

EEM iShares: MSCI Emerging Markets Index (Equity)

DJCBTI United States: Dow Jones CBOT Treasury Index (Bonds)

GREXP Germany: REX-Performance Index (Bonds)BG05.L United Kingdom: Gilt All Index (Bonds)GLD United States: SPDR Gold Shares (Commodities)

PAveDD

Portfolio optimisation with average draw down constraint

Description

This function returns the result of a long-only portfolio optimization whereby the portfolio's (historic) average draw down is constrained to an upper limit.

Usage

```
PAveDD(PriceData, AveDD = 0.1, softBudget = FALSE, ...)
```

Arguments

PriceData A rectangular array of price data.

AveDD Numeric, the upper bound of the average portfolio draw down.

softBudget Logical, whether the budget constraint shall be implemented as a soft constraint,

i.e. the sum of the weights can be less than one. The default is to use an equality

constraint.

... Arguments are passed down to Rglpk_solve_LP

Details

This function implements a long-only portfolio optimisation with an average draw down constraint (see references below). The problem can be stated in the form of a linear program and GLPK is used as solver.

Value

An object of formal class "PortAdd".

20 PCDaR

Note

A warning is issued in case the solver had exit status not equal to zero.

## End(Not run)</pre>
```

PCDaR

Portfolio optimisation with conditional draw down at risk constraint

Description

This function returns the result of a long-only portfolio optimization whereby the portfolio's (historic) conditional draw down at risk is constrained to an upper limit.

Usage

```
PCDaR(PriceData, alpha = 0.95, bound = 0.05, softBudget = FALSE, ...)
```

Arguments

PriceData /	A rectangular	array of	price data.
-------------	---------------	----------	-------------

alpha Numeric, the confidence level for which the conditional draw down shall be

computed.

bound Numeric, the upper bound of the conditional draw down.

softBudget Logical, whether the budget constraint shall be implemented as a soft constraint,

i.e. the sum of the weights can be less than one. The default is to use an equality

constraint.

... Arguments are passed down to Rglpk_solve_LP

PERC 21

Details

This function implements a long-only portfolio optimisation with a CDaR constraint (see references below). The problem can be stated in the form of a linear program and GLPK is used as solver.

Value

An object of formal class "PortAdd".

Note

A warning is issued in case the solver had exit status not equal to zero.

Examples

PERC

Equal risk contributed portfolios

Description

This function solves for equal risk contributed portfolio weights.

Usage

```
PERC(Sigma, par = NULL, percentage = TRUE, ...)
```

PERC PERC

Arguments

Sigma Matrix, the variance-covariance matrix of asset returns

par Vector, the initial values of the weights.

percentage Logical, whether the weights shall be returned as decimals or percentages (de-

fault).

... Ellipsis argument is passed down to nlminb().

Details

The objective function is the standard deviation of the marginal risk contributions, which is minimal, *i.e.* zero, if all contributions are equal. The weights are rescaled to sum to unity.

Value

An object of formal class "PortSol".

Note

The optimisation is conducted by calling nlminb(). Hereby, the arguments lower = 0 and upper = 1 have been specified.

Author(s)

Bernhard Pfaff

References

```

PERC2 23

PERC2	Equal risk contributed portfolios (alternative)
LINCZ	Equal risk contributed portfolios (alternative)

Description

This function solves for equal risk contributed portfolio weights by employing the solnp() function.

Usage

```
PERC2(Sigma, par = NULL, percentage = TRUE, ...)
```

Arguments

Sigma Matrix, the variance-covariance matrix of asset returns

par Vector, the initial values of the weights.

percentage Logical, whether the weights shall be returned as decimals or percentages (de-

fault).

... Ellipsis argument is passed down to solnp().

Details

The objective function is the standard deviation of the marginal risk contributions, which is minimal, *i.e.* zero, if all contributions are equal. The weights are rescaled to sum to unity. The lower and upper bounds are set to LB = rep(0, N) and UB = rep(1, N), respectively.

Value

An object of formal class "PortSol".

Note

The optimisation is conducted by calling sonlp() contained in the package **Rsolnp**. Hereby, the arguments LB = 0 and UB = 1 have been specified.

plot-methods

Methods for Function plot in Package graphics

Description

Additional arguments to the plot-method pertinent to the defined S4-classes in this package are detailed below.

Usage

```
## S4 method for signature 'PortDD'
plot(x, main = NULL, xlab = NULL, ylab = NULL,
col = c("black", "red"), grid = TRUE, invert = TRUE, ...)
```

Arguments

x	PortDD: an object that belongs to this virtual class.
main	character: The title of the plot.
xlab	character: The description of the x-axis.
ylab	character: The description of the y-axis.
col	character: Two-element vector of the names of the colors for the portfolio's draw downs and the optimal level.
grid	Logical: Whether to superimpose a grid on the plot.
invert	Logical: Whether the draw downs shall be plotted as negative numbers; the default is TRUE.
	Ellipsis argument is passed to the generic plot function.

Author(s)

Bernhard Pfaff

26 PMaxDD

PMaxDD	Portfolio optimisation with maximum draw down constraint

Description

This function returns the result of a long-only portfolio optimization whereby the portfolio's (historic) draw down is constrained to an upper limit.

Usage

```
PMaxDD(PriceData, MaxDD = 0.1, softBudget = FALSE, ...)
```

Arguments

PriceData A rectangular array of price data.

MaxDD Numeric, the upper bound of the maximum draw down.

softBudget Logical, whether the budget constraint shall be implemented as a soft constraint,

i.e. the sum of the weights can be less than one. The default is to use an equality

constraint.

... Arguments are passed down to Rglpk_solve_LP

Details

This function implements a long-only portfolio optimisation with a maximum draw down constraint (see references below). The problem can be stated in the form of a linear program and GLPK is used as solver.

Value

An object of formal class "PortMdd".

Note

A warning is issued in case the solver had exit status not equal to zero.

## End(Not run)</pre>
```

PMD

Most Diversified Portfolio

Description

This function returns the solution of the most diversified portfolio (long-only).

Usage

```
PMD(Returns, percentage = TRUE, ...)
```

Arguments

Returns A rectangular array of return data.

percentage Logical, whether the weights shall be returned as decimals or percentages (de-

fault).

... Arguments are passed down to cov().

Details

The optimisation problem is akin to that of a global minimum-variance portfolio, but instead of using the variance-covariance matrix of the asset returns, the correlation matrix is utilised as dispersion measure. The weights are then recovered by rescaling the optimal solution with the assets' standard deviations and normalizing, such that the weights sum to one.

Value

An object of formal class "PortSol".

Note

The optimisation is conducted by calling solve.QP().

PMinCDaR

Portfolio optimisation for minimum conditional draw down at risk

Description

This function returns the result of a long-only portfolio optimization whereby the portfolio's (historic) conditional draw down at risk is minimized.

Usage

```
PMinCDaR(PriceData, alpha = 0.95, softBudget = FALSE, ...)
```

Arguments

PriceData A rectangular array of price data.

alpha Numeric, the confidence level for which the conditional draw down shall be

computed.

softBudget Logical, whether the budget constraint shall be implemented as a soft constraint,

i.e. the sum of the weights can be less than one. The default is to use an equality

constraint.

... Arguments are passed down to Rglpk_solve_LP

Details

This function implements a long-only portfolio optimisation for a minimum conditional draw down at risk (see references below). The problem can be stated in the form of a linear program and GLPK is used as solver.

Value

An object of formal class "PortAdd".

PMTD 29

Note

A warning is issued in case the solver had exit status not equal to zero.

PMTD

Minimum Tail Dependent Portfolio

Description

This function computes the solution of a minimum tail dependent portfolio (long-only).

Usage

```
PMTD(Returns, method = c("EmpTC", "EVT"), k = NULL, percentage = TRUE, ...)
```

Arguments

Returns	A rectangular array of return data.
method	Character, the type of non-parametric estimation.
k	Integer, the threshold value for the order statistic. If left NULL, then $k = sqrt(nrow(x))$ is used.
percentage	Logical, whether the weights shall be returned as decimals or percentages (default).
	Arguments are passed down to rank.

30 PortAdd-class

Details

Akin to the optimisation of a global minimum-variance portfolio, the minimum tail dependennt portfolio is determined by replacing the variance-covariance matrix with the matrix of the lower tail dependence coefficients as returned by tdc.

Value

An object of formal class "PortSol".

Note

The optimisation is conducted by calling solve.QP().

Examples

PortAdd-class

Class "PortAdd"

Description

This class is intended to hold the results from a portfolio optimisation with a constraint on its average draw down.

Objects from the Class

Objects can be created by calls of the form new("PortAdd", ...). This class extends the "PortSol" class.

Slots

AveDD: Numeric, the average draw down.

DrawDown: timeSeries, the hsitoric portfolio's draw downs.

weights: Numeric, vector of optimal weights.

opt: List, the result of the call to GLPK.

type: Character, the type of the optimized portfolio.

call: The call to the function that created the object.

PortCdd-class 31

Extends

```
Class "PortSol", directly.

PortCdd-class

Class "PortCdd"

Description

This class is intended to hold the results from a portfolio optimisation with a constraint on its average draw down.

Objects from the Class

Objects can be created by calls of the form new("PortCdd", ...). This class extends the "PortSol" class.

Slots

CDaR: Numeric, the conditional draw down at risk.

thresh: Numeric, threshold value for draw downs at the α level.

DrawDown: timeSeries, the hsitoric portfolios draw downs.

weights: Numeric, vector of optimal weights.

opt: List, the result of the call to GLPK.

type: Character, the type of the optimized portfolio.

call: The call to the function that created the object.

Extends

```
Class "PortSol", directly.

34 PortSol-class

PortSol-class

Class "PortSol"

Description

This class is intended to hold the results for the weights of an optimal portfolio. Currently, this class is used for minimum-variance and equal-risk-contributed portfolios. It can further be used to store the results of optimal factor weights according to one of the aforementioned portfolio types.

Objects from the Class

Objects can be created by calls of the form new("PortSol", ...).

Slots

```
weights: Numeric, vector of optimal weights.
```

opt: List, the result of the call to the optimizing function.

type: Character, the type of the optimized portfolio.

call: The call to the function that created the object.

Methods

show signature(object = "PortSol"): Returns the portfolio type as text with the optimal weights from the object.

Solution signature(object = "PortSol"): Returns the list object of the optimizer, *i.e.* the slot opt from the object.

Weights signature(object = "PortSol"): Returns the list object of the optimizer, *i.e.* the slot weights from the object.

update signature(object = "PortSol"): updates object by calling the issuing function with
 altered arguments.

Author(s)

Bernhard Pfaff

```
showClass("PortSol")
```

returnconvert 35

Description

Either continuous returns or discrete returns can be converted into the other type.

Usage

```
returnconvert(y, convdir = c("cont2disc", "disc2cont"), percentage = TRUE)
```

Arguments

y Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts

are supported.

convdir Character, the type of return conversion.

percentage Logical, if TRUE (the default) the returns, y, are expressed as percentages.

Value

An object of the same class as y, containing the converted returns.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = ''matrix'' The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y ="numeric" Calculation of the returns.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the returns. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the returns. The attributes are preserved and an object of the same class is returned.
- y = "zoo" Calculation of the returns. The attributes are preserved and an object of the same class is returned.

Author(s)

Bernhard Pfaff

36 returnseries

Examples

returnseries

Continuous and discrete returns

Description

Either continuous returns or discrete returns are computed for an object. The returns can be expressed as percenatges and the first NA value can be trimmed.

Usage

Arguments

trim

У	Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.
method	Character, the type of return to be computed.

percentage Logical, if TRUE (the default) the returns are expressed as percenatges.

Logical, if FALSE (the default) the first value is set to NA such that the length of

the return series coincides with the length of the series in levels.

compound Logical, if FALSE (the default), then simple returns are computed and otherwise

compounded returns.

Value

An object of the same class as y, containing the truncated series.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = "matrix" The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the es trend.

Socp 37

- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the returns. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the returns. The attributes are preserved and an object of the same class is returned
- y = "zoo" Calculation of the returns. The attributes are preserved and an object of the same class is returned.

Author(s)

Bernhard Pfaff

Examples

```
data(StockIndex)
y <- StockIndex[, "SP500"]
ret <- returnseries(y)
head(ret)</pre>
```

Socp

Second-order Cone Programming

Description

The function solves second-order cone problem by primal-dual interior point method. It is a wrapper function to the C-routines written by Lobo, Vandenberghe and Boyd (see reference below).

Usage

```
Socp(f, A, b, C, d, N,
    x = NULL, z = NULL, w = NULL, control = list())
```

Arguments

f	Vector defining linear objective, length(f)==length(x)
Α	Matrix with the A_i vertically stacked: $A = [A_1; A_2;; A_L]$.
b	Vector with the b_i vertically stacked: $b = [b_1; b_2; \dots; b_L]$.
С	Matrix with the c_i' vertically stacked: $C = [c_1'; c_2'; \dots; c_L']$.
d	Vector with the d_i vertically stacked: $d = [d_1; d_2; \dots; d_L]$.
N	Vector of size L, defining the size of each constraint.
Х	Primal feasible initial point. Must satisfy: $ A_i * x + b_i < c_i' * x + d_i$ for
	$i=1,\ldots,L.$
Z	Dual feasible initial point.
W	Dual feasible initial point.
control	A list of control parameters.

38 Socp

Details

The primal formulation of an SOCP is given as:

$$minimisef' * x$$

subject to

$$||A_i * x + b_i|| \le c_i' * x + d_i$$

for $i=1,\ldots,L$. Here, x is the $(n\times 1)$ vector to be optimised. The dual form of an SOCP is expressed as:

$$maximise \sum_{i=1}^{L} -(b'*z_i + d_i*w_i)$$

subject to

$$\sum_{i=1}^{L} (A_i' * z_i + c_i * w_i) = f$$

and

$$||z_i|| = w_i$$

for $i = 1, \dots, L$, given strictly feasible primal and dual initial points.

The algorithm stops, if one of the following criteria is met:

- 1. abs.tol maximum absolute error in objective function; guarantees that for any x: $abs(f' * x f' * x_opt) \le abs_tol$.
- 2. rel.tol maximum relative error in objective function; guarantees that for any x: $abs(f'*x-f'*x_opt)/(f'*x_opt) <= rel_tol(iff'*x_opt>0)$. Negative value has special meaning, see target next.
- 3. target if $rel_tol < 0$, stops when f' * x < targetor b' * z >= target.
- 4. max.iter limit on number of algorithm outer iterations. Most problems can be solved in less than 50 iterations. Called with max_iter = 0 only checks feasibility of x and z, (and returns gap and deviation from centrality).
- 5. The target value is reached. rel_tol is negative and the primal objective p is less than the target.

Value

A list-object with the following elements:

x Solution to the primal problem.
 z Solution to the dual problem.
 iter Number of iterations performed.
 hist see out_mode in SocpControl.

convergence A logical code. TRUE indicates successful convergence.

info A numerical code. It indicates if the convergence was successful.

message A character string giving any additional information returned by the optimiser.

SocpControl 39

Note

This function has been ported from the **Rsocp** package contained in the Rmetrics-Project on R-Forge. In contrast to the former implementation, allowance is made for specifying more than one cone constraint.

SocpControl	Control Variables for Socp	

Description

This function returns a list object of control parameters that are passed down to the C-function SOCP. It's default values are used in Socp.

Usage

Arguments

abs.tol	Absolute tolerance.
rel.tol	Relative tolerance.
target	Target value < 0 , only used if rel.tol < 0 .
max.iter	The maximum number of iterations, socp is aborted if more are required for convergence.
Nu	The parameter that controls the rate of convergence, Nu > 1, recommended range 5 to 50.
out.mode	Specifies what should be output: 0 - nothing, 1 - duality gap for initial point and after each iteration, 2 - duality gap and deviation from centrality, for initial point and after each iteration.
BigM.K	Iterataion parameter. The default values is BigM.K = 2.
BigM.iter	Iterataion parameter. The default values is BigM.iter = 5.

40 SocpPhase1

Details

For details about these control parameters, the reader is referred to the reference below, in particular sections 2.7, 2.8 and 4.3 to 4.5. A pdf-version of the user's guide is shipped in the packages doc subdirectory.

Value

A list object with the control parameters.

Note

This function has been ported from the **Rsocp** package contained in the Rmetrics-Project on R-Forge.

Author(s)

Bernhard Pfaff

SocpPhase1

SOCP: Initialising objective variable x in primal form

Description

This function determines values for x, whence they have not been specified by the user. Here, a feasibility problem is solved first and its solution is then used as an initial point for the original problem.

Usage

```
SocpPhase1(f, A, b, N, control)
```

Arguments

Ť	vector:	the	parameters	of	the	objective	function in i	its]	primal fo	rm.
---	---------	-----	------------	----	-----	-----------	---------------	-------	-----------	-----

A matrix; the parameter matrix of the cone constraints.
b vector: the parameter vector of the cone constraints.

N vector: the count of rows pertinent to each cone constraint.

control list: the list of control parameters for SOCP.

SocpPhase2 41

Details

The finding of an initial point x is described in the user's guide, sectionb 2.8.

Value

A vector with the initial point for x.

Note

This function has been ported from the **Rsocp** package contained in the Rmetrics-Project on R-Forge.

Author(s)

Bernhard Pfaff

References

Lobo, M. and Vandenberghe, L. and Boyd, S., *SOCP: Software for Second-order Cone Programming, User's Guide*, Beta Version, April 1997, Stanford University.

SocpPhase2

SOCP: Initialising objective variable z in dual form

Description

This function determines values for z, whence they have not been specified by the user.

Usage

```
SocpPhase2(f, A, b, N, x, control)
```

Arguments

f	vector: the parameters of the objective function in its primal form.
Α	matrix; the parameter matrix of the cone constraints.
b	vector: the parameter vector of the cone constraints.
N	vector: the count of rows pertinent to each cone constraint.
x	vector: initial point of SOCP in its primal form.
control	list: the list of control parameters for SOCP.

42 SP500

Value

A vector with the initial point for z (dual form of SOCP).

Note

This function has been ported from the **Rsocp** package contained in the Rmetrics-Project on R-Forge.

Author(s)

Bernhard Pfaff

References

Lobo, M. and Vandenberghe, L. and Boyd, S., SOCP: Software for Second-order Cone Programming, User's Guide, Beta Version, April 1997, Stanford University.

SP500

Standard & Poor's 500

Description

Weekly price data of 476 S&P 500 constituents.

Usage

data(SP500)

Format

A data frame with 265 weekly observations of 476 members of the S&P 500 index. The sample starts at 2003-03-03 and ends in 2008-03-24.

Details

The data set was used in the reference below. The authors adjusted the price data for dividends and have removed stocks if two or more consecutive missing values were found. In the remaining cases the NA entries have been replaced by interpolated values.

sqrm

Square root of a quadratic matrix

Description

This function returns the square root of a quadratic and diagonalisable matrix.

Usage

```
sqrm(x, ...)
```

Arguments

x matrix, must be quadratic.

... The ellipsis argument is passed down to eigen().

Details

The computation of the square root of a matrix is based upon its eigen values and corresponding eigen vectors. The square matrix A is diagonisable if there is a matrix V such that $D = V^{-1}AV$, whereby D is a diagonal matrix. This is only achieved if the eigen vectors of the $(n \times n)$ matrix A constitute a basis of dimension n. The square root of A is then $A^{1/2} = VD^{1/2}V'$.

Value

A matrix object and a scalar in case a (1×1) matrix has been provided.

tdc

Tail Dependence Coefficient

Description

This function returns the pairwise tail dependence coefficients between N series. The TDCs are estimated non-parametrically by either the empirical tail copula or based on the stable tail-dependence function.

Usage

```
tdc(x, method = c("EmpTC", "EVT"), lower = TRUE, k = NULL, ...)
```

Arguments

X	Matrix, or an object that can be coerced to it.
method	Character, the type of non-parametric estimation.
lower	Logical, if TRUE (default), lower TDC are computed and upper TDC, else.
k	Integer, the threshold value for the order statistic. If left NULL, then $k = sqrt(nrow(x))$ is used.
	Ellipsis, arguments are passed down to rank.

Details

For a matrix or an object that can be coerced to it with ncol(x) >= 2, the pair wise tail dependencies are estimated non-parametrically and returned as a symmetric matrix. The threshold value k is the upper/lower bound for the order statistics to be considered. The diagonal elements are always equal to one, because a series has a dependence of one with itself, of course.

Value

A matrix with the tail dependent coefficients.

Bilson Trend

Description

Calculation of the Bilson Trend as a technical trading indicator.

Usage

```
trdbilson(y, exponent)
```

Arguments

y Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts

are supported.

exponent Numeric, the value for α in the equation below.

Details

The Bilson trend is calculated according to the formula:

$$z = sign(y) \times |y|^{(1-|y|^{\alpha})}$$

Value

An object of the same class as y, containing the computed Bilson trend values.

48 trdbinary

Methods

y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.

- y = "matrix" The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- **v** = "**numeric**" Calculation of the bilson trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.
- y = "zoo" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.

trdbinary

Binary Trend

Description

Calculation of the Binary Trend as a technical trading indicator.

Usage

```
trdbinary(y)
```

trdbinary 49

Arguments

У

Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.

Details

The Binary trend is calculated according to the formula:

$$z = sign(y) \times \min(|4/\pi \arctan(y)|, 1)$$

Value

An object of the same class as y, containing the computed Binary trend values.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = ''matrix'' The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the binary trend.
- **y** = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the binary trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the binary trend. The attributes are preserved and an object of the same class is returned.
- **y = "zoo"** Calculation of the binary trend. The attributes are preserved and an object of the same class is returned.

Exponentially Smoothed Trend

Description

Calculation of the exponentially smoothed trend as a technical trading indicator.

Usage

```
trdes(y, lambda, init = NULL)
```

Arguments

У	Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.
lambda	Numeric, the smoothing parameter for λ in the equation below. The value for the parameter must be in the interval $0 < \lambda < 1$.
init	The initial value in the recursive calculation of the filter. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default, <i>i.e.</i> NULL, is a set of zeros.

Details

The exponetially smoothed trend is calculated according to the formula:

$$z_t = \lambda y_t + (1 - \lambda) * z_{t-1}$$

Value

An object of the same class as y, containing the computed exponetially smoothed values.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = "matrix" The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the es trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- **y = "zoo"** Calculation of the es trend. The attributes are preserved and an object of the same class is returned.

head(es)</pre>
```

trdhp

Hodrick-Prescott Filter

Description

Calculation of the Hodrick-Prescott filter as a technical trading indicator.

Usage

```
trdhp(y, lambda)
```

Arguments

y Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts

are supported.

lambda Numeric, the value for λ in the equation below.

Details

The Hodrick-Prescott filter is calculated according to the formula:

$$\min(\tau_t) = \sum_{t=1}^{T} (y_t - \tau_t)^2 + \lambda \sum_{t=2}^{T-1} (\Delta^2 \tau_{t+1})^2$$

Value

An object of the same class as y, containing the computed Hodrick-Prescott values.

52 trdsma

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = ''matrix'' The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the bilson trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.
- y = "zoo" Calculation of the bilson trend. The attributes are preserved and an object of the same class is returned.

trdsma

Simple Moving Average

Description

Calculation of a right ended simple moving average with equal weights determined by n.periods.

Usage

```
trdsma(y, n.periods, trim = FALSE)
```

trdsma 53

Arguments

У	Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.
n.periods	Integer, the number of periods to be included in the calculation of the simple moving average.
trim	Logical, if FALSE (the default) the first value is set to NA, otherwise the object is trimmed by the first obeservation.

Value

An object of the same class as y, containing the computed simple moving averages.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = "matrix" The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the es trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- **y = "zoo"** Calculation of the es trend. The attributes are preserved and an object of the same class is returned.

54 trdwma

trdwma	Weighted Moving Average	

Description

Calculation of a right ended weighted moving average with weights according to weights.

Usage

```
trdwma(y, weights, trim = FALSE)
```

Arguments

У	Objects of classes: numeric, matrix, data.frame, ts, mts, timeSeries, zoo and xts are supported.
weights	Numeric, a vector containing the weights.
trim	Logical, if FALSE (the default) the first value is set to NA, otherwise the object is trimmed by the first obeservation.

Details

If the sum of the weights is greater than unity, a warning is issued.

Value

An object of the same class as y, containing the computed weighted moving averages.

Methods

- y = "data.frame" The calculation is applied per column of the data.frame and only if all columns are numeric.
- y = "matrix" The calculation is applied per column of the matrix.
- y = "mts" The calculation is applied per column of the mts object. The attributes are preserved and an object of the same class is returned.
- y = "numeric" Calculation of the es trend.
- y = "timeSeries" The calculation is applied per column of the timeSeries object and an object of the same class is returned.
- y = "ts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- y = "xts" Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
- **y = "zoo"** Calculation of the es trend. The attributes are preserved and an object of the same class is returned.
